1 General information

Risk budgets are a central tool to estimate and manage the portfolio risk allocation. They decompose total portfolio risk into the risk contribution of each position. Boudt et al. (2010) propose several portfolio allocation strategies that use an appropriate transformation of the portfolio Conditional Value at Risk (CVaR) budget as an objective or constraint in the portfolio optimization problem. This document explains how risk allocation optimized portfolios can be obtained under general constraints in the PortfolioAnalytics package of ?.

PortfolioAnalytics is designed to provide numerical solutions for portfolio problems with complex constraints and objective sets comprised of any R function. It can e.g. construct portfolios

that minimize a risk objective with (possibly non-linear) per-asset constraints on returns and drawdowns (Carl et al., 2010). The generality of possible constraints and objectives is a distinctive characteristic of the package with respect to RMetrics fPortfolio of Wuertz et al. (2010). For standard Markowitz optimization problems, use of fPortfolio rather than PortfolioAnalytics is recommended.

PortfolioAnalytics solves the following type of problem

$$\min_{w} g(w) \quad s.t. \quad \begin{cases}
h_1(w) \le 0 \\
\vdots \\
h_q(w) \le 0.
\end{cases}$$
(1)

PortfolioAnalytics first merges the objective function and constraints into a penalty augmented objective function

$$L(w) = g(w) + \text{penalty} \sum_{i=1}^{q} \lambda_i \max(h_i(w), 0),$$
(2)

where λ_i is a multiplier to tune the relative importance of the constraints. The default values of penalty and λ_i (called multiplier in PortfolioAnalytics) are 10000 and 1, respectively.

The minimum of this function is found through the *Differential Evolution* (DE) algorithm of Storn and Price (1997) and ported to R by Mullen et al. (2009). DE is known for remarkable performance regarding continuous numerical problems (Price et al., 2006). It has recently been advocated for optimizing portfolios under non-convex settings by Ardia et al. (2010) and Yollin (2009), among others. We use the R implementation of DE in the DEoptim package of Ardia and Mullen (2009).

The latest version of the PortfolioAnalytics package can be downloaded from R-forge through the following command:

install.packages("PortfolioAnalytics", repos="http://R-Forge.R-project.org")

Its principal functions are:

- constraint(assets,min,max,min_sum,max_sum): the portfolio optimization specification starts with specifying the shape of the weight vector through the function constraint. The weights have to be between min} and \verbmax" and their sum between min_sum and max_sum. The first argument assets is either a number indicating the number of portfolio assets or a vector holding the names of the assets.
- add.objective(constraints, type, name): constraints is a list holding the objective to be minimized and the constraints. New elements to this list are added by the function add.objective. Many common risk budget objectives and constraints are prespecified and can be identified by specifying the type and name.

- constrained_objective(w, R, constraints): given the portfolio weight and return data, it evaluates the penalty augmented objective function in (2).
- optimize.portfolio(R,constraints): this function returns the portfolio weight that solves the problem in (1). R is the multivariate return series of the portfolio components.
- optimize.portfolio.rebalancing(R,constraints,rebalance_on,trailing_periods: this function solves the multiperiod optimization problem. It returns for each rebalancing period the optimal weights and allows the estimation sample to be either from inception or a moving window.

Next we illustrate these functions on monthly return data for bond, US equity, international equity and commodity indices, which are the first 4 series in the dataset indexes. The first step is to load the package PortfolioAnalytics and the dataset. An important first note is that some of the functions (especially optimize.portfolio.rebalancing) requires the dataset to be a xts object (Ryan and Ulrich, 2010).

```
> library(PortfolioAnalytics)
```

- > data(indexes)
- > class(indexes)

```
[1] "xts" "zoo"
```

- > indexes <- indexes[,1:4]</pre>
- > head(indexes,2)

US Bonds US Equities Int'l Equities Commodities

```
      1980-01-31
      -0.0272
      0.0610
      0.0462
      0.0568

      1980-02-29
      -0.0669
      0.0031
      -0.0040
      -0.0093
```

> tail(indexes,2)

US Bonds US Equities Int'l Equities Commodities

In what follows, we first illustrate the construction of the penalty augmented objective function. Then we present the code for solving the optimization problem.

2 Setting of the objective function

2.1 Weight constraints

```
> # create the portfolio specification object
> Wcons <- portfolio.spec( assets = colnames(indexes[,1:4]) )
> # Add box constraints
> Wcons <- add.constraint( portfolio=Wcons, type='box', min = 0, max=1 )
> # Add the full investment constraint that specifies the weights must sum to 1.
> Wcons <- add.constraint( portfolio=Wcons, type="full_investment")</pre>
```

Given the weight constraints, we can call the value of the function to be minimized. We consider the case of no violation and a case of violation. By default, normalize=TRUE which means that if the sum of weights exceeds max_sum, the weight vector is normalized by multiplying it with sum(weights)/max_sum such that the weights evaluated in the objective function satisfy the max_sum constraint.

```
> constrained_objective( w = rep(1/4,4) , R = indexes[,1:4] , portfolio = Wcons)

[1] 0
> constrained_objective( w = rep(1/3,4) , R = indexes[,1:4] , portfolio = Wcons)

[1] 0
> constrained_objective( w = rep(1/3,4) , R = indexes[,1:4] , portfolio = Wcons, normalize=FALSE)

[1] 3333.333
```

The latter value can be recalculated as penalty times the weight violation, that is: $10000 \times 1/3$.

2.2 Minimum CVaR objective function

Suppose now we want to find the portfolio that minimizes the 95% portfolio CVaR subject to the weight constraints listed above.

```
> ObjSpec = add.objective( portfolio = Wcons , type="risk",name="CVaR",
+ arguments=list(p=0.95), enabled=TRUE)

The value of the objective function is:
> constrained_objective( w = rep(1/4,4) , R = indexes[,1:4] , portfolio = ObjSpec)
```

[,1]

ES 0.1253199

This is the CVaR of the equal-weight portfolio as computed by the function ES in the PerformanceAnalytics package of Carl and Peterson (2009)

- > library(PerformanceAnalytics)
- > out<-ES(indexes[,1:4],weights = rep(1/4,4),p=0.95, portfolio_method="component")
- > out\$MES

[,1]

[1,] 0.1253199

All arguments in the function ES can be passed on through arguments. E.g. to reduce the impact of extremes on the portfolio results, it is recommended to winsorize the data using the option clean="boudt".

```
> out<-ES(indexes[,1:4],weights = rep(1/4,4),p=0.95,clean="boudt", portfolio_method="component")
> out$MES
```

[,1]

[1,] 0.07124999

For the formulation of the objective function, this implies setting:

```
> ObjSpec = add.objective( portfolio = Wcons , type="risk",name="CVaR",
```

- + arguments=list(p=0.95,clean="boudt"), enabled=TRUE)
- > constrained_objective(w = rep(1/4,4) , R = indexes[,1:4] , portfolio = ObjSpec)

[,1]

ES 0.07124999

An additional argument that is not available for the moment in ES is to estimate the conditional covariance matrix trough the constant conditional correlation model of Bollerslev (1990).

For the formulation of the objective function, this implies setting:

```
> ObjSpec = add.objective( portfolio = Wcons , type="risk",name="CVaR",
```

- + arguments=list(p=0.95,clean="boudt"), enabled=TRUE, garch=TRUE)
- > constrained_objective(w = rep(1/4,4) , R = indexes[,1:4] , portfolio = ObjSpec)

[,1]

ES 0.07638508

2.3 Minimum CVaR concentration objective function

Add the minimum 95% CVaR concentration objective to the objective function:

```
> ObjSpec = add.objective( portfolio = Wcons , type="risk_budget_objective",name="CVaR",
```

+ arguments=list(p=0.95,clean="boudt"), min_concentration=TRUE, enabled=TRUE)

The value of the objective function is:

```
> constrained_objective( w = rep(1/4,4) , R = indexes[,1:4] , portfolio = ObjSpec)
```

[1] 0

We can verify that this is effectively the largest CVaR contribution of that portfolio as follows:

```
> ES(indexes[,1:4],weights = rep(1/4,4),p=0.95,clean="boudt", portfolio_method="component")
```

\$MES

[,1]

[1,] 0.07124999

\$contribution

```
US Bonds US Equities Int'l Equities Commodities 0.000593884 0.020748329 0.024636472 0.025271304
```

\$pct_contrib_MES

```
US Bonds US Equities Int'l Equities Commodities 0.008335215 0.291204659 0.345775103 0.354685023
```

2.4 Risk allocation constraints

We see that in the equal-weight portfolio, the international equities and commodities investment cause more than 30% of total risk. We could specify as a constraint that no asset can contribute more than 30% to total portfolio risk. This involves the construction of the following objective function:

```
> ObjSpec = add.objective( portfolio = Wcons , type="risk_budget_objective",name="CVaR", max_prisk
+ arguments=list(p=0.95,clean="boudt"), enabled=TRUE)
> constrained_objective( w = rep(1/4,4) , R = indexes[,1:4] , portfolio = ObjSpec)
```

[1] 1004.601

This value corresponds to the penalty parameter which has by default the value of 10000 times the exceedances: $10000 * (0.045775103 + 0.054685023) \approx 1004.601$.

3 Optimization

The penalty augmented objective function is minimized through Differential Evolution. Two parameters are crucial in tuning the optimization: search_size and itermax. The optimization routine

- 1. First creates the initial generation of NP= search_size/itermax guesses for the optimal value of the parameter vector, using the random_portfolios function generating random weights satisfying the weight constraints.
- 2. Then DE evolves over this population of candidate solutions using alteration and selection operators in order to minimize the objective function. It restarts itermax times.

It is important that search_size/itermax is high enough. It is generally recommended that this ratio is at least ten times the length of the weight vector. For more details on the use of DE strategy in portfolio allocation, we refer the reader to Ardia et al. (2010).

3.1 Minimum CVaR portfolio under an upper 40% CVaR allocation constraint

The functions needed to obtain the minimum CVaR portfolio under an upper 40% CVaR allocation constraint are the following:

```
> ObjSpec <- constraint(assets = colnames(indexes[,1:4]),min = rep(0,4),
+ max=rep(1,4), min_sum=1,max_sum=1 )
> ObjSpec <- add.objective_v1( constraints = ObjSpec, type="risk",
+ name="CVaR", arguments=list(p=0.95,clean="boudt"),enabled=TRUE)
> ObjSpec <- add.objective_v1( constraints = ObjSpec,
+ type="risk_budget_objective", name="CVaR", max_prisk = 0.4,
+ arguments=list(p=0.95,clean="boudt"), enabled=TRUE)
> set.seed(1234)
> out = optimize.portfolio_v1(R= indexes[,1:4],constraints=ObjSpec,
+ optimize_method="DEoptim",itermax=10, search_size=2000)
```

After the call to these functions it starts to explore the feasible space iteratively:

```
      Iteration:
      1 bestvalit:
      0.029506 bestmemit:
      0.810000

                                                            0.108170
                                                                        0.010000
                                                                                     0.140000
Iteration: 8 bestvalit: 0.028874 bestmemit:
                                                0.692069
                                                            0.028575
                                                                        0.100400
                                                                                     0.071600
Iteration: 9 bestvalit: 0.028874 bestmemit:
                                                0.692069
                                                            0.028575
                                                                        0.100400
                                                                                     0.071600
Iteration: 10 bestvalit: 0.028874 bestmemit:
                                                 0.692069
                                                             0.028575
                                                                         0.100400
                                                                                      0.071600
elapsed time:1.85782111114926
```

If TRACE=FALSE the only output in out is the weight vector that optimizes the objective function.

> out[[1]]

```
US Bonds US Equities Int'l Equities Commodities 0.77530240 0.03201150 0.11247491 0.08021119
```

If TRACE=TRUE additional information is given such as the value of the objective function and the different constraints.

3.2 Minimum CVaR concentration portfolio

The functions needed to obtain the minimum CVaR concentration portfolio are the following:

- > ObjSpec <- constraint(assets = colnames(indexes[,1:4]) ,min = rep(0,4),
- + max=rep(1,4), min_sum=1,max_sum=1)
- > ObjSpec <- add.objective_v1(constraints = ObjSpec,
- + type="risk_budget_objective", name="CVaR",
- + arguments=list(p=0.95,clean="boudt"),
- + min_concentration=TRUE, enabled=TRUE)
- > set.seed(1234)
- > out = optimize.portfolio_v1(R= indexes[,1:4],constraints=ObjSpec,
- + optimize_method="DEoptim",itermax=50, search_size=5000)

The iterations are as follows:

Iteration:	1 bestvalit:	0.010598	bestmemit:	0.800000	0.100000	0.118000	0.030000
Iteration:	2 bestvalit:	0.010598	bestmemit:	0.800000	0.100000	0.118000	0.030000
Iteration:	3 bestvalit:	0.010598	bestmemit:	0.800000	0.100000	0.118000	0.030000
Iteration:	4 bestvalit:	0.010598	bestmemit:	0.800000	0.100000	0.118000	0.030000
Iteration:	5 bestvalit:	0.010598	bestmemit:	0.800000	0.100000	0.118000	0.030000

```
Iteration: 45 bestvalit: 0.008209 bestmemit:
                                                 0.976061
                                                              0.151151
                                                                          0.120500
                                                                                       0.133916
Iteration: 46 bestvalit: 0.008170 bestmemit:
                                                 0.897703
                                                              0.141514
                                                                          0.109601
                                                                                       0.124004
Iteration: 47 bestvalit: 0.008170 bestmemit:
                                                 0.897703
                                                              0.141514
                                                                          0.109601
                                                                                       0.124004
Iteration: 48 bestvalit: 0.008170 bestmemit:
                                                              0.141514
                                                                          0.109601
                                                                                       0.124004

This portfolio has the equal risk contribution characteristic:

\$contribution

US Bonds	US Equities I	nt'l Equities	Commodities
0.008169565	0.008121930	0.008003228	0.008167917

\$pct_contrib_MES

US Bonds	US Equities In	t'l Equities	Commodities
0.2516605	0.2501931	0.2465366	0.2516098

3.3 Dynamic optimization

Dynamic rebalancing of the risk budget optimized portfolio is possible through the function optimize.portfolio.rebalancing. Additional arguments are rebalance_on\ which indicates the rebalancing or through moving window estimation, where each window has trailing_periods observations.

The minimum number of observations in the estimation sample is specified by training_period.

Its default value is 36, which corresponds to three years for monthly data.

As an example, consider the minimum CVaR concentration portfolio, with estimation from in inception and monthly rebalancing. Since we require a minimum estimation length of total number of observations -1, we can optimize the portfolio only for the last two months.

- > set.seed(1234)
- > out = optimize.portfolio.rebalancing_v1(R= indexes,constraints=ObjSpec, rebalance_on ="months",
- + optimize_method="DEoptim",itermax=50, search_size=5000, training_period = nrow(indexes)-1)

For each of the optimization, the iterations are given as intermediate output:

```
Iteration: 1 bestvalit: 0.010655 bestmemit:
                                                0.800000
                                                            0.100000
                                                                         0.118000
                                                                                     0.030000

Of course, DE is a stochastic optimizaer and typically will only find a near-optimal solution that depends on the seed. The function optimize.portfolio.parallel in PortfolioAnalytics allows to run an arbitrary number of portfolio sets in parallel in order to develop "confidence bands" around your solution. It is based on Revolution's foreach package (Computing, 2009).
